Projection Breakdown as a Closed Mechanical Loop

Intimacy does not suspend the system's base physics.

It forces the base equation to run under maximum relational load.

Projection breakdown is not a psychological failure,

nor a problem of communication, attachment, or maturity.

It is a closed mechanical sequence: predictable, repeatable, and structurally necessary.

Once projection begins, the room is no longer operating in ordinary multi-source mode.

It is operating in single-input mode:

- projector dominant
- Spotlight suppressed
- table-surface stabilized
- Position-3 correction delayed
- reality admitted only through the ice-water pathway

Under these conditions, every projection cycle follows the same loop:

$\Delta \rightarrow$ projector activation $\rightarrow$ Position-3 ice-water generation $\rightarrow$ shadow leakage / melt $\rightarrow$ pressure accumulation $\rightarrow$ automatic shutdown

Once Δ is registered, the projector activates automatically.

Once the projector is active, Position-3 begins generating corrective leakage.

Once leakage and melt exceed the room's tolerance, pressure rises.

Once pressure reaches operational limit, the room shuts down.

This volume does not describe how relationships should function.

It describes the internal physics governing the lifespan of projection.

Volume XV closes the loop opened in Volume I by showing that the same universal sequence governing symbolic load also governs projection breakdown.

Intimacy does not override the base equation.

It forces the system to run it at full voltage.

Mirror Activation: Why One Alarm Always Triggers the Other

After projection shutdown, Alarm becomes the system's primary governing module.

Once one partner's Alarm activates, the other partner's activation becomes mechanically likely.

This is not emotional reciprocity.

It is output–input coupling between two partially visible, high-pressure systems.

1. Alarm activation always produces defensive output

Alarm never stays internal.

Once a threat is tagged,
the system emits defensive output such as:

- contraction
- coldness
- withdrawal
- hardened tone
- heightened reactivity

These outputs are not emotions.

They are the room's immediate threat-management behaviours.

Alarm does not wait for interpretation.

It acts through output.

2. With the Spotlight half-restored, intention is unreadable

Because the Spotlight has not regained full luminosity,
the partner cannot read intention.

Only observable behaviour enters the field.

Under half-light conditions:

- nuance is lost
- context is weakened
- defensive behaviour is stripped of internal explanation

The receiving system therefore processes not intention,
but deviation.

And under Alarm, deviation is computed as:

inconsistent

→ unpredictable

→ threatening

3. Defensive output becomes threat input in the partner's system

The first system's defense is received by the second system as incoming aggression-signature.

What one system generates as protection,
the other system receives as:

- rejection
- hostility
- distancing
- attack
- disruption of relational safety

Thus:

your defense = their threat input

This is not miscommunication in the ordinary sense.

It is a deterministic cross-system conversion.

4. Threat input automatically recruits the partner's Alarm

Once the second system receives aggression-tagged input, its own Alarm module activates.

No emotional interpretation is required.

The chain is mechanical:

A Alarm activates

→ A outputs defense

A defense enters B as threat input

→ B Alarm activates

B outputs defense

→ B defense enters A as threat input

This is the onset of mirrored Alarm recruitment.

5. The system locks into Double-Alarm Coupling

Once both Alarms are active:

- your defense = their threat
- their defense = your threat
- each output recruits the other's Alarm
- amplification replaces interpretation
- the loop becomes self-sustaining

This configuration is:

Double-Alarm Coupling.

At this point, neither system is relating through meaning.

Both systems are relating through threat-response output.

The cycle cannot stop through clarification alone,

because the room is still operating below full visibility.

Summary line

In intimate systems, one Alarm never stays alone.

Once one partner enters defense, the other is mechanically pulled into activation.

Symbolic Locking: Why Two People Cannot Disconnect While the Symbols Remain Seated

Projection shutdown does not terminate the relational field.

As long as the symbolic objects remain seated,
the system cannot complete disengagement.

Symbolic Locking is the structural condition
in which two systems remain relationally active
while simultaneously unable to repair, exit, or re-stabilize.

1. Seated symbols keep the relationship mechanically active

Projection is offline,
but the symbolic structure remains intact:

- Seat 1 — being seen / being held
- Seat 2 — sustaining or completing the other
- Seat 4 — shared future potential

If these objects remain seated,
the relationship remains active inside the room.

The projector may be gone,
but the relational geometry has not yet been cleared.

2. Residual heat prevents exit because no free energy remains

The room is still operating under high-pressure conditions:

- temperature remains elevated

- Position-3 leakage persists
- symbolic vibration continues
- defensive regulation stays active
- Alarm consumes active bandwidth

Exit requires free operational energy.

But in this state, energy is already consumed by:

- Alarm activation
- defensive output
- misreading correction attempts
- boundary maintenance
- symbolic containment of the still-seated objects

Thus the system can maintain tension,
but it cannot complete withdrawal.

3. Half-lit Spotlight makes repair impossible

Under insufficient visibility:

- actions are classified as threat before they are read as meaning
- deviations are amplified
- communication collapses into misinterpretation
- corrective signals cannot stabilize the field

Repair requires enough visibility

to separate intention from output

and meaning from threat-signature.

That computation cannot run under partial illumination.

Therefore the field cannot move forward into repair.

4. Alarm pushes outward while the symbols pull inward

Two forces now operate simultaneously:

- Alarm → increase distance

- seated symbols → maintain bond continuity

This produces a real mechanical contradiction:

- pulled inward
- pushed outward
- overheated
- unable to settle
- unable to disengage

This is not emotional confusion.

It is force conflict inside an unresolved relational field.

5. System outcome: no exit, no closure, no clarity, no separation

With the symbolic objects still in place:

- exit cannot complete
- detachment cannot finalize
- repair cannot compute
- field collapse cannot finish

The relationship becomes trapped in a midline orbit:

- not together
- not apart
- not repaired
- not ended

This is Symbolic Locking.

Summary line

As long as the symbolic objects remain seated,
the relationship cannot conclude, even when both systems are already in pain.

The intimate-adversary configuration is not the guaranteed end of a
relationship,

but it is the final mechanical checkpoint before one of two later outcomes becomes possible:

repair after visibility recovery

or

separation after symbolic clearing.

For the architecture itself, this is the terminal locked state.
